Abstract: In this paper, by using adequate stress-strain relationship, mesh elements, boundary conditions and loading conditions, the finite element ANSYS analysis on the behavior of circular tubes subjected to symmetrical cyclic bending with or without external pressure is discussed. The behavior includes the moment-curvature and ovalization-curvature relationships. In addition, the calculated ovalizations at two different sections, middle and right cross-sections, are also included. Experimental data for 6061-T6 aluminum alloy tubes subjected to cyclic bending with or without external pressure were compared with the ANSYS analysis. It has been shown that the analysis of the elastoplastic moment-curvature relationship and the symmetrical, ratcheting and increasing ovalization-curvature relationship is in good agreement with the experimental data.

Key words: Cyclic bending, external pressure, moment, curvature, ovalization, finite element ANSYS analysis.

1. Introduction

In many engineering applications, such as offshore pipelines, risers, platforms, land-based pipelines, and breeder reactor tubular components are acted upon both cyclic bending and external pressure. It is well known that the ovalization of the tube cross-section is observed when a circular tube is subjected to bending. If the loading history is cyclic bending, the ovalization increases in a ratcheting manner with the number of cycles. However, if the bending is combined with the external pressure, a small amount of external pressure will strongly influence the trend and magnitude of the ovalization. Therefore, the experimental and theoretical studies of the response of circular tubes under cyclic bending combined with external pressure are important for many industrial applications.

Pan and his co-workers [6] also constructed a similar bending machine with a newly invented measurement apparatus, which was designed and set up by Pan et al. [6], to study various kinds of tubes under different cyclic bending conditions. Lee et al. [7] studied the influence of the $D_i/t$ (diameter/thickness) ratio on the response and stability of circular tubes.

Corona and Kyriakides [10] experimentally investigated the response of 6061-T6 aluminum alloy tubes under cyclic bending and external pressure. In their study, the moment-curvature curve revealed a cyclic hardening for 6061-T6 aluminum alloy tube. The moment-curvature curve became steady after a few cycles. In addition, the moment-curvature response exhibits almost no influence by the external pressure. However, the ovalization-curvature behavior increases in a ratcheting symmetrical manner and is strongly influenced by the magnitude of the external pressure. Although Lee et al. [11] used endochronic theory combined with the principle of virtual work to properly simulate the aforementioned behavior, there are several flaws in their theoretical formulation. Firstly, the endochronic theory is too complicated and when it is combined with the principle of virtual work, the numerical method for determining the related parameters becomes extremely difficult. Next, their method treats the same response for every cross section for a circular tube under pure bending. However, based on the experimental data from Corona and Kyriakides [10], the moment and curvature are almost the same for every section, but the ovalization is different for each section. In addition, the response of the 6061-T6 aluminum alloy tube lacks of investigation.

Due to the great progress in computation speed and great improvement in the theory describing the elastoplastic response in finite element method in recent years, the accuracy of calculation by finite element method has become better [4-5, 12-13]. In this study, by considering adequate stress-strain relationships, mesh elements, boundary conditions and loading conditions, the finite element software ANSYS is used to analyze the response of circular tubes subjected to cyclic bending with or without external pressure. Circular tube for 6061-T6 aluminum alloy is considered in this study. The experimental data tested by Corona and Kyriakides [10] are used to compare with the finite element ANSYS analysis. It has been shown that good agreement between the ANSYS analysis and experimental results has been achieved.

2. Finite Element ANSYS Analysis

In this study, the finite element software package ANSYS is used for analyzing the behavior of circular tubes subjected to cyclic bending with or without external pressure. The behavior is the relationships among the moment, curvature and ovalization. The elastoplastic stress-strain relationships, mesh element, boundary condition and loading condition of the finite element ANSYS are discussed in the following.

2.1 Elastoplastic Stress-Strain Relationship

According to the uniaxial stress-strain curves for 6061-T6 aluminum alloy tested by Corona and Kyriakides [10], the uniaxial stress ($\sigma$)-strain ($\varepsilon$) curves are constructed in ANSYS as shown in Fig. 1. It can be seen that the curve is constructed by multilinear segments, the number on the curve indicates the order of the segment. In addition, the kinematic hardening rule is used as the hardening rule for cyclic loading.

2.2 Mesh Element

Due to the three-dimensional geometry and elastoplastic deformation of the tube, we use the SOLID 185 element for relative analysis. This element is a tetrahedral element built in ANSYS and is suitable for analyzing the plastic or large deformation. In particular, this element is adequate to analyze a shell component under bending. Due to the symmetry of the front and rear, right and left, only one fourth of the tube’s model was constructed. Fig. 2 is the mesh of the finite element ANSYS.
2.3 Boundary and Loading Conditions

Based on the coordinate system of Fig. 2, the pure bending is on the $y$-$z$ plane. The points on the top and bottom of the tube are free to move in $y$-direction and $z$-direction. But they can not move in $x$-direction. Fig. 3 shows the boundary condition of the finite element ANSYS. It can be seen that we use rollers on the top and bottom of the tube to represent the constraints.

In this study, the pure bending is controlled by curvature. The magnitude of the curvature cannot be directly input into ANSYS. Therefore, the corresponding displacements of the points (1, 2, ..., $N$) on the center surface (neutral surface) are considered as the input data shown in Fig. 4. The points of the undeformed center surface are indicated as 1, 2, ..., $N$. Once the tube is subjected to pure bending, the points 1, 2, ..., $N$ move to points $1'$, $2'$, ..., $N'$, respectively. For pure bending, the curvature $\kappa$ is:

$$\kappa = \frac{1}{\rho} = \frac{\theta}{L} \quad (1)$$

where, $\rho$ is the radius of curvature and $L$ is the half of the original tube’s length. Since the loading is curvature-controlled, the magnitudes of $\kappa$, $\rho$ and $L$ are known quantities. Thus, the magnitude of $\theta$ can be determined from Eq. (1). The vertical displacement of point 1 is:

$$\theta_1 = \rho - \rho \cos \theta \quad (2)$$

The horizontal displacement of point 1 equals zero. When we consider the displacement of point 2, the...
Finite Element ANSYS Analysis of the Behavior for 6061-T6 Aluminum Alloy Tubes under Cyclic Bending with External Pressure

length $l_2$ is a known quantity, the angle of $\theta_{12}$ is determined to be:

$$\theta_{12} = \tan^{-1}\left(\frac{l_2}{O_1}\right) = \tan^{-1}\left(\frac{l_2}{\rho \cos \theta}\right)$$

(3)

The length $O_2$ is found to be

$$O_2 = \sqrt{l_2^2 + O_1^2} = \sqrt{l_2^2 + (\rho \cos \theta)^2}$$

(4)

The length of $O_2'$ is determined as:

$$O_2' = \rho - O_2$$

(5)

The vertical and horizontal displacements of $O_2$ are calculated to be:

$$v_{2v} = O_2 \cos \theta_{12}, \quad v_{2h} = O_2 \sin \theta_{12}$$

(6)

For the displacement of point $N$, the quantities of $\theta_{1N}$, $ON$, $NN'$ are determined to be:

$$\theta_{1N} = \tan^{-1}\left(\frac{N}{\rho \cos \theta}\right), \quad ON = \sqrt{N^2 + (\rho \cos \theta)^2}$$

$$NN' = \rho - ON$$

(7)

The vertical and horizontal displacements of $NN'$ are calculated to be:

$$v_{NN'} = NN' \cos \theta_{1N}, \quad v_{NN'} = NN' \sin \theta_{1N}$$

(8)

3. Comparison and Discussion

In this section, the behavior of 6061-T6 aluminum alloy circular tubes under cyclic bending with or without external pressure tested by Corona and Kyriakides [10] is compared with the finite element ANSYS analysis discussed in Section 2. In their experimental result, the magnitudes of the pressure, moment, and curvature are normalized by the following quantities [10]:

$$P_e = \frac{2E}{1 - \nu^2}\left(\frac{t}{D_o}\right)^3, \quad M_o = 3\sigma_o D_o^2 t, \quad \kappa_i = \frac{t}{D_o^2}$$

(9)

where, $E$ is the elastic modulus, $\nu$ is the Poisson’s ratio, $D_o$ is the original outside diameter, $t$ is the wall-thickness, and $\sigma_o$ is the yield strength. For 6061-T6 aluminum alloy tube, the values of $E$, $\nu$, $D_o$, $t$ and $\sigma_o$ are 68.3 GPa, 0.33, 0.03091 m, 0.00089 m and 288 MPa, respectively [10].

3.1 Cyclic Bending without External Pressure

Fig. 5a presents the experimental result of cyclic moment ($M/M_o$)-curvature ($\kappa/\kappa_i$) curve for 6061-T6 aluminum alloy tube under curvature-controlled cyclic bending. The external pressure in this case is equal to zero. The $D_o/t$ ratio is 34.7 and the cyclic curvature range is from +0.67 m$^{-1}$ to -0.67 m$^{-1}$. It is observed from the experimental $M/M_o, \kappa/\kappa_i$ curve that the 6061-T6 aluminum alloy tube shows a steady loop on the first cycle. Fig. 5b shows the corresponding simulated result obtained from ANSYS analysis. It can be seen that there is not any cyclic hardening or
Finite Element ANSYS Analysis of the Behavior for 6061-T6 Aluminum Alloy Tubes under Cyclic Bending with External Pressure

softening built in ANSYS, thus, only a loop of the $M/M_0$-$\kappa/\kappa_1$ curve represents all cyclic bending responses. Fig. 6a depicts the corresponding experimental ovalization of tube cross-section ($\Delta D/D_0$) as a function of the applied curvature ($\kappa/\kappa_1$) for Fig. 5a where $\Delta D$ is the change in outside diameter. It can be noted that the ovalization of tube cross-section increases in a symmetrical ratcheting manner with the number of cycles. As the cyclic process continues, the ovalization keeps accumulating. Fig. 6b is the corresponding simulated result of $\Delta D/D_0$-$\kappa/\kappa_1$ curve.

3.2 Cyclic Bending with External Pressure

Fig. 7a presents the experimental result of cyclic moment ($M/M_0$)-curvature ($\kappa/\kappa_1$) curve for 6061-T6 aluminum alloy tube under cyclic bending with a constant external pressure $P_c$ of 1.47 MPa. The cyclic curvature range is from +0.43 m$^{-1}$ to -0.43 m$^{-1}$. Fig. 7b demonstrates the corresponding ANSYS analysis result. In their experimental study [10], the length of the tube was around 24$D_o$. They measured the ovalization at the position of 11$D_o$ indicated as point A and 18$D_o$ indicated as point B from the right (Fig. 8a). They discovered that the ovalization at point A (shown in Fig. 8a) increases slower than that at point B (shown in Fig. 9a). Figs. 8b and 9b show the corresponding simulation result of $\Delta D/D_o$-$\kappa/\kappa_1$ curve at point A and B, respectively.

4. Conclusions

In this study, the finite element ANSYS with adequate stress-strain relationship, mesh elements, boundary conditions and loading conditions was used to simulate the response of circular tubes subjected cyclic bending with or without external pressure. The experimental data of 6061-T6 aluminum alloy tubes tested by Corona and Kyriakides [10] were used for comparison with the ANSYS analysis. It can be seen that the elastoplastic cyclic loops for moment-curvature relationship and the symmetrical, ratcheting and increasing ovalization-curvature relationship were properly simulated in Figs. 5b-8b, respectively. In addition, the ovalization at different position can also be well simulated in Fig. 9b.
