Abstract: We here present the results of photocurrent from BAs. The photocurrent in this system had been calculated by using the free-electron and muffin-tin potentials. Schrodingers' equation has been solved by using these potentials to obtain the necessary initial and final state wave-functions for the electrons to evaluate the matrix element for transitions. From the calculations it is observed that variation of photocurrent showed trends obtained as in the case of metals like tungsten, aluminium, molybdenum, copper etc.

Key words: Wien2k, DFT (Density functional theory), muffin-tin, FP-LAPW.

1. Introduction

Boron Arsenide is a wide band gap semiconductor compound in the III-V family and occurs as cubic sphalerite. This compound crystallizes in zinc-blende structure [1]. It has a number of technological applications such as solar cells, space electronics and devices that produce electrical energy by coupling a radioactive beta emitter to a semiconductor junction. In this paper here, we present study of photoemission from BAs by using the muffin-tin potential model. In photoemission, the incident radiation excites the electrons lying at the Fermi level or below it. The photo-excited electrons gain sufficient energy to overcome the work function of the metal and hence comes out into the vacuum to contribute to photocurrent. For evaluation of the vector potential involved in the matrix element for transition from initial to final state, we require real and imaginary

dielectric constants. These had been calculated by using the density functional theory (DFT) based on full-potential approximation which is implemented in wien2k code [2].

2. Methodology

In our study of photoemission from BAs, the current density for photoemission is calculated by using the golden-rule approximations [3] as:

$$\frac{dj(E)}{d\Omega} = \frac{2\pi}{\hbar c} \sum_{f,i} |\langle \Psi_f | H' | \Psi_i \rangle|^2 \delta(E - E_F) \delta(E_f - E_i - \hbar\omega) f_0(E - \hbar\omega) [1 - f_0(E)] \quad (1)$$

where, Ψ_i and Ψ_f are the initial and final states wave-function and $H' = (e/2mc)(A \cdot p + p \cdot A)$, A being the vector potential and p the one-electron momentum operator. In order to evaluate the matrix element, we need to construct Ψ_i and Ψ_f and determine A . Although the one-electron states are treated quite accurately in many photoemission calculations [4], the variation of the photon field in the surface region is usually neglected and hence we have

used a simple model for field calculations as done by Bagchi and Kar [5].

We have used the muffin-tin potential to derive the initial state wave function Ψ_i [6] used in Eq. (1), which is given by

$$\Psi_i(\vec{r}) = \begin{cases} \sum_L A_{1L} f_{1L}(R) Y_L(\theta, \phi), & \text{spherical region} \\ \sum_{\vec{g}} [u_{\vec{g}} e^{iK_{\vec{g}}^+ \cdot \vec{R}} + V_{\vec{g}} e^{i\vec{K}_{\vec{g}}^- \cdot \vec{R}}], & \text{interstitial region} \end{cases} \quad (2)$$

where, $K_{\vec{g}}^+ = \left[(\vec{k} + \vec{g})_{\parallel} \pm \sqrt{2(E_i - V_0) - |\vec{k} + \vec{g}|_{\parallel}^2} \right]$ and $\vec{R} = \vec{r} - \vec{C}_j$.

Similarly, the final state wavefunction [6] can be written as

$$\Psi_f(\vec{r}) = \begin{cases} \left[e^{igz} + \frac{g-k_f}{g+k_f} e^{-igz} e^{i\vec{k}_1 \cdot \vec{r}_1} \right] e^{i\vec{k}_{\parallel} \cdot \vec{r}_{\parallel}}, & z > 0 \\ \frac{2g}{g+k_f} e^{ik_f z} e^{i\vec{k}_{\parallel} \cdot \vec{r}_{\parallel}}, & z < 0 \end{cases} \quad (3)$$

where, $\vec{k}_f^2 = \frac{2mE_f}{\hbar^2} - \vec{k}_{\parallel}^2$, $\vec{g}^2 = \frac{2m}{\hbar^2} (E_f - V_0) - \vec{k}_{\parallel}^2$,

$E_f = E_i + \hbar\omega$.

The initial state wavefunction used for the free-electron model [7] is given by:

$$\Psi_i(\vec{r}) = \begin{cases} \left[e^{ik_i z} + \frac{ik_i z + \chi}{ik_i z - \chi} e^{-ik_i z} \right] e^{-\vec{k}_{\parallel} \cdot \vec{r}_{\parallel}}, & z < 0 \\ \frac{2ik_i}{ik_i - \chi} e^{-\chi z} e^{\vec{k}_{\parallel} \cdot \vec{r}_{\parallel}}, & z > 0 \end{cases} \quad (4)$$

where, $\vec{k}_{\parallel}$ and $\vec{r}_{\parallel}$ are the components of $\vec{k}$ and $\vec{r}$ in the X-Y plane i.e. the plane parallel to the surface. The final state wavefunction is as given in Eq. 3.

3. Results and Discussion

We have computed our results for normal photoemission from the surface and bulk states of BAs as a function of photon energy. Hence the initial state energy $E_i = 6.098$ eV, $E_F = 7.319$ eV, potential energy $V_0 = 15.95$ eV, work function $\phi = 8.631$ eV, surface width $a = 5.298$ Å, angle of incident radiation $\theta_i = 45^\circ$ and scattering factor $\alpha = 0.35$. For

calculations of the electromagnetic fields which is related to vector potential, we have used the real and dielectric constants calculated by using the full-potential linearized augmented plane wave method implemented in Wien2k code [2] which is based on the density functional theory [8].

In Fig. 1, we show the plot of photocurrent as a function of photon energy of the incident radiation from the first and second surface layers of the medium. In this calculation, dielectric constants ϵ_1 and ϵ_2 were obtained by using the Wien2k code with GGA approximation [8]. For the case of photoemission from the first surface layer, we find that photocurrent increases as photon energy increases and this becomes maximum at photon energy 10 eV. With the increase in photon energy, we find that photocurrent decreases and showed small humps at photon energies 13 eV and 17 eV photon eV. Photocurrent was minimum at 22 eV incident photon radiation energy. Again, beyond 22 eV energy, the photocurrent showed rise in photocurrent with the increase of incident radiation. The second maxima in photocurrent occurred at 28 eV photon energy after which it decreases gradually.

In Fig. 1, we have plotted photocurrent as a function of photon energy for BAs from the second layer of the system. The trend in photocurrent is different than in the case of photoemission from the

Fig. 1 Plot of photocurrent in BAs as a function of photon energy from the first two layers.

Fig. 2 Plot of photocurrent in BAs as function of photon energy using free-electron-model.

first surface layer. Photocurrent simply rises with an increase of photon energy and at 26 eV photon energy, there is occurrence of peak in photocurrent. Photocurrent decreases with the further increase in photon energy after 26 eV and becomes minimum. Contribution of photocurrent from second layer showed similar trends as from the first layer, but occurrence of peaks are at different photon energies.

In Fig. 2, we show the plot of photocurrent as a function of incident photon energy for the values of same parameters as used above in the case of BAs but by using the free electron potential [9]. The same values of dielectric constants as used in the case of surface layer calculations above was used. The results of photocurrent here showed features similar to the case of metals like beryllium and aluminium as was obtained by Thapa et al earlier [7, 9, 10]. For example, there is maxima in photocurrent at 12 eV photon energy and photocurrent decreased with the increase of photon energy. At photon energy 22.5 eV, there was occurrence of minima in photocurrent. Beyond the increase in photocurrent from 22.5 eV, we find there is also an occurrence of second maxima in photocurrent but of very small height comparable to the one at 12 eV. After this the photocurrent decreases gradually with the increase in photon energy the features similarly observed in the case beryllium, aluminium etc. [11]

We may conclude that the surface variation of photon field is important in calculating the photocurrent cross-section also in the case of BAs. This fact had been also observed by Bagchi and Kar [5] in the case of tungsten. They have found that vector potential component in the surface region decreases greatly near the plasma frequency ω_p of the solids. This explains the decrease in normal photoemission from the surface states near ω_p [5].

3. Conclusions

From photoemission study of BAs, we found that the behaviour of photocurrent from the first and second layers are similar in nature, although occurrence of maxima in photocurrent is at different photon energies. Occurrence of peaks can be correlated with the peaks in density of states of electron from various energy levels with the help of density functional theory. Works in this direction are in progress which will be reported soon.
