Arduino Based Planar Two DoF Robot Manipulator

Fatih Cemal Can

Mechatronics Engineering Department, Faculty of Engineering and Architecture, Izmir Katip Çelebi University, Izmir 35620, Turkey

Abstract: In this research, two DoF five bar robot manipulator is controlled by using a human-machine interface program working in a computer. The human machine interface program is developed in Visual C#. Net environment after completing inverse kinematic analysis of the robot manipulator. Human machine interface in computer screen calculates two rotational joint variables for given positions of the robot end point. Then the computer program sends a data package containing these joint variables to Arduino microcontroller. Arduino microcontroller set the position of two servo motors according to calculated joint angles. Any position in workspace can be obtained by using the algorithm. The robot can follow trajectories such as a line, a circle and a rectangle. Furthermore, a lot of patterns can be generated using function with variable radius and angle of rotation.

Key words: Two DoF robot manipulator, five-bar, Arduino, Visual C#.

1. Introduction

The five-bar linkage mechanism applications have been used in different engineering fields. Researchers working in mechatronics, biomedical, mechanical, electrical and electronics engineering fields designed and implemented the five-bar mechanism in their published investigations. Inverse kinematics, link design, medical application, dynamic simulation, calibration and performance were topics of research interest on the five-bar linkage mechanism. Some studies about these topics are presented as follows.

As a biomedical engineering application, a laparoscopic robotic camera system based on five-bar linkage was designed and tested by Kobayashi et al. [1]. This robotic system reduces the process time for different surgical operations if human assisted camera system is compared to robot assisted the camera system.

Hybrid five-bar mechanism was investigated by researchers [2, 3]. A dynamic simulation and control of these kinds of mechanism was carried out in Simmechanics of Matlab by Zi et al. [3]. The five-bar was driven by a constant velocity motor and servo motor in this study. The aim of the study was to control tracking trajectory of the end point of the mechanism via traditional Proportional-Derivative (PD) Control and closed loop PD-type iterative learning control.

Inverse kinematics analysis of six different five-bar planar parallel manipulators which were RRRRR, RRRRP, PRRRP, RPRPR, RRRPR and RPRRP was presented by Alici [4]. Sylvester elimination method was used to solve the set of nonlinear equations in his study.

Villarreal-Cervantesand et al. [5] optimized design parameters of a five-bar parallel robot by using a novel mechatronic design approach. They designed kinematic and dynamic parameters of the five-bar’s links with respect to desired trajectories [5, 6].

A position accuracy calibration of a five-bar planar parallel robot (DexTAR) was established by Joubair et al. [7]. Experimental validation setup was constructed and the position error reduced to 0.08 mm within the entire robot workspace of 600 mm × 600 mm.

A real-time control of a five-bar parallel robot (DexTAR) was studied using dynamic model of the robot to implement minimum time trajectory planning by Bourbonnais et al. [8]. They used working mode region to reach points of pick and place operations.

Corresponding author: Fatih Cemal Can, Ph.D., assistant professor, research fields: mechanism design, parallel manipulators.
Several working modes are considered to reach the same pick and place points in their study.

In this study, a five-bar linkage was designed and two links of the mechanism were produced by using 3D printer. In Section 2, the inverse kinematics analysis of five-bar manipulator will be presented. In the next section human machine interface design and control algorithm will be explained. In Section 4 electronic hardware and circuit are illustrated along with figures. Then, experimental test results will be presented in Section 5. Finally, a conclusion will be drawn at the end of the study.

2. Inverse Kinematic Analysis of the Robot Manipulator

Five-bar mechanism has two degrees of freedom according to Grubler formulation. In inverse kinematics, end point location (P) is known in Fig. 1. Using this location, two input angles $\theta_1$ and $\theta_2$ must be calculated. This problem can be solved by dividing manipulator into two serial RR manipulators.

From the first serial kinematic chain, vector loop closure Eq. (1) is as follows,

$$O_0O_1 + O_1A + AP = O_0P$$

Second, the second serial kinematic chain, vector loop closure Eq. (2) is as follows,

$$O_0O_2 + O_2B + BP = O_0P$$

In this study, the user of the robot manipulator changes $O_0P$ vector in human machine interface. However these equations are dependent on each joint angle related to kinematic chain. In order to compute input angles, other joint variables must be eliminated.

$$d_{x1} + i d_{y1} + L_1 e^{i\theta_1} + L_3 e^{i\theta_3} = P_x + i P_y$$

$$d_{x2} + i d_{y2} + L_2 e^{i\theta_2} + L_4 e^{i\theta_4} = P_x + i P_y$$

Rearranging Eq. (3), angle which is need to be eliminated is kept alone,

$$L_3 e^{i\theta_3} = (P_x - d_{x1}) - i(P_y - d_{y1}) - L_1 e^{i\theta_1}$$

The offset distances in Eq. (5) can be combined with the end coordinates as follows,

$$L_3 e^{i\theta_3} = (P_x - d_{x1}) - i(P_y - d_{y1}) - L_1 e^{i\theta_1}$$

Conjugate of Eq. (6) is written as follows,

$$L_3 e^{-i\theta_3} = (P_x - d_{x1}) - i(P_y - d_{y1}) - L_1 e^{-i\theta_1}$$

Multiplying Eqs. (6) and (7), angle $\theta_3$ is able to be eliminated.

$$L_3 e^{-i\theta_3} = (P_x - d_{x1}) - i(P_y - d_{y1}) - L_1 e^{-i\theta_1}$$

Remember that ($e^{i\theta} + e^{-i\theta}$ equals to $2\cos(\theta)$ and ($e^{i\theta} + e^{-i\theta}$) equals to $2\sin(\theta)$ in Eq. (8). The equation can be simplified using these equalities as follows,

$$A \cos(\theta_3) + B \sin(\theta_3) + C = 0$$

where $A = -2(P_x - d_{x1})$ and $B = -2(P_y - d_{y1})$ and $C = (P_x - d_{x1})^2 + (P_y - d_{y1})^2 + L_1^2 - L_3^2$. Half-tangent rule can be used for this equation in order to solve one unknown.

$$\cos(\theta_2) = \frac{1 - t_3^2}{1 + t_3^2}, \sin(\theta_2) = \frac{2t_3}{1 + t_3^2} \text{ and } t_2 = \tan(\theta_3)$$

$$C - A) + 2B + t_3 + C + A = 0$$

Two different roots are able to be obtained from the equation. Discriminant must be real for physically realizable result.

$$\text{dis}1 = \sqrt{4B^2 - 4(C^2 - A^2)}$$

One unknown $t_1$ in Eq. (10) is calculated using discriminant which is found in Eq. (11).

$$t_1 = \frac{(-4B + \text{dis}1)}{2(C - A)}$$

One can compute the angle using half tangent value.
Once $\theta_1$ is known, other angle of kinematic chain is calculated as follows,

$$\theta_3 = \arctan\left(\frac{P_y - d_{y1}}{P_x - d_{x1} - L_1 \cos(\theta_1)}\right)$$ \hspace{1cm} (14)

Similarly, applying same process to the second kinematic chain, we can obtain the discriminant as follows,

$$\text{dis}^2 = \sqrt{4E^2 - 4(F^2 - D^2)} \hspace{1cm} (15)$$

where $D = -2(P_x - d_{x2})L_2$, $E = -2(P_y - d_{y2})L_2$, and $F = (P_x - d_{x2})^2 + (P_y - d_{y2})^2 + L_2^2 - L_4^2$.

Similar to previous solution, unknown of the second kinematic chain is now known using equation as follows,

$$t_2 = \frac{-4E \mp \text{dis}^2}{2(F - D)} \hspace{1cm} (16)$$

Using discriminant in Eq. (16), angle of rotation is to be,

$$\theta_2 = 2 \tan(t_2) \hspace{1cm} (17)$$

Other angle of the second kinematic chain,

$$\theta_4 = \arctan\left(\frac{P_y - d_{y2} - L_2 \cos(\theta_2)}{P_x - d_{x2} - L_2 \sin(\theta_2)}\right)$$ \hspace{1cm} (18)

Two solutions are obtained for each angle. Totally four different modes can be found for the robot. These modes of robot can be found from researches [7, 8]. However, our robot is working on just one mode which is shown in Fig. 1.

3. Visual C# Interface Design and Program for Human-Machine Interaction

The program of the robot is constructed on kinematic analysis of the robot. Two coordinates of the end point location are inputs for this program. User is able to use mouse cursor in order to define end point location of the robot. User must click mouse left button on the Form then the user must move cursor on the form canvas. Program solves angles according to end point location simultaneously and redraws lines of the robot.

Human machine interface consists of two parts. The first part is the interface design of the program. This part is related to graphical drawing of the robot, angles in text boxes and control buttons and output of the program. The design of the program is illustrated in Fig. 2.
The second part is algorithm or coding. Follow chart of the visual program is depicted in Fig. 3. This code is written using events of graphical objects such as buttons, lines, form and buttons. This kind of programming is named event based programming. We use load, mouse down, mouse move and mouse up events for our code.

Start: Form1_Load event is working. In this event, link lengths and other constant parameters are defined.

Input: Form1_Mousedown, Form1_MouseMove and Form1_MouseUp events are working.

Calculate: dis1 and dis2 are calculated according to inverse kinematic analysis of the robot.

Are roots of dis1 and dis2 real? Program must decide that the results are physically realizable or not. Non real results cannot be used in real environment. Therefore, they are unnecessary.

Calculate: If roots are real, angles are calculated using Eqs. (13), (14), (17) and (18).

Prepare and send data packages to Arduino: When two angles are calculated, they are packaged in order for sending. The data package includes plus and minus symbols which show the direction of the rotation, and two digit numbers which indicate magnitude of the rotation.

One Data Package

| + 9 0 - 4 5 |

Is Arduino serial connection OK?: In order to send packages to Arduino, COM port number of Arduino must be valid and connected. Baud rate of the connection must be selected correctly.

Is close of Form clicked?: The program runs until close of form is clicked. The program ends if it is clicked.

The flow chart of Arduino program is illustrated in Fig. 4. This code waits for the input from interface program, separate according to data package format and sends these to servo motors.

Non real results cannot be used in real environment. Therefore, they are unnecessary.
4. Electronic Hardware and Circuit

Arduino Mega 1280 Micro Controller is used to control the robot. The robot has two servos connected to digital pins 9 and 10 which are used as PWM (pulse width modulation) of arduino. The electronic circuit of the robot is seen in Fig. 5. This circuit is created in Autodesk Circuit Online (New name is Tinkercad) Software. Arduino Uno is used in the circuit because Arduino mega is not available in this software. One 5 V DC power source must be used to supply required power to servo motors. The Arduino code can be simulated in the program. The Arduino code can be verified and output can be observed.

5. The Robot Construction and Test Results

The robot is constructed using two Emax ES 3005 water proof servo motors and 3-D printed parts. Two link lengths $L_1$ and $L_2$ are chosen same (20 mm) because they are servo links packaged in servo motor box. Other two link lengths $L_3$ and $L_4$ are selected to be same (30 mm). Distance between shafts of two servo motors is 19 mm. The final mechanical and electronic setup is depicted in Fig. 6.

5.1 Drawing a line and a Rectangle

Both two shapes are the most basic task to test our robot. Simply, pencil translates forward and backward between two points to draw a line and four lines are used to draw a rectangle (Fig. 7). We defined the length of the line as 20 mm in the program. The straightness of the line was good but the length of the line was nearly 19.20 mm. This dimension error depends on joint clearances and friction at the joints.

Next, the rectangle was drawn. Fillets are created by our robot at the corner. This rectangle was not perfect dimensioned similar to the line. But straightness and appearance of the rectangle is acceptable.

Next, the rectangle was drawn. Fillets are created by our robot at the corner. This rectangle was not perfect dimensioned similar to the line. But straightness and appearance of the rectangle is acceptable.
5.2 Computer Aided Free Hand Drawing

We tried to test our robot manipulator using human machine interface (HMI). User entered required points from HMI, points were sent to microcontroller and microcontroller set angles of two servo motors. Acceptable outputs were obtained as seen from Figs. 8 and 9. We firstly tried to draw a letter and then a spiral. The letter and the shape are very close to original shape which is drawn on HMI.

5.3 Drawing a Pattern

In this section a circular pattern drawing will be explained along with examples. We created the pattern by using equations as follows.

\[
P_x = 60 + r \cos \left( \beta \frac{\pi}{180} \right) \tag{19}
\]

\[
P_y = 60 + r \sin \left( \beta \frac{\pi}{180} \right) \tag{20}
\]

where \(P_x\) and \(P_y\) are coordinates of the end point of the robot, \(r\) is radius of circle, \(\beta\) is angle of the rotation.

Fig. 8 Free hand drawing of letter A; (a) input from human-machine interface, (b) output on the paper.

Fig. 9 Free hand drawing of a spiral; (a) input from human-machine interface, (b) output on the paper.

of radius. If radius is constant and \(\beta\) angle is changing uniformly in Eqs. (19) and (20), we will get a circle. However, if radius is changed according to a linear function \((r = r + a \times k\), if \(r > 90\) then \(k = -1\), if \(r < 1\) then \(k = +1\)) and also changing rotation of angle \((\beta = \beta + dt)\), the patterns can be drawn. According to this pattern configuration and formulation, the end-effector of five-bar robot drew the patterns shown in Fig. 10.

6. Conclusion

The five-bar robot manipulator was constructed and tested in this study. Two servo motors of the robot were controlled using HMI program through Arduino microcontroller. Test results were shown for a line, a rectangle, free hand drawing and patterns. Cost of our robot manipulator is very low (it is nearly 50$) compared to other robot manipulators. Readability and appearance of the test shapes are good. However, accuracy and repeatability are not very well. Therefore,
they must be improved. Due to its cost, this robot manipulator will be useful to explain the working principle of the five-bar robot manipulator and application of the robot to engineering students. Other observations from the project have been obtained as follows:

Our program is working using original Arduino Mega with ATmega16U2 USB communication chip for a while. Even that the baudrate is changed to maximum, original Arduino cannot get respond to our program after some time. However Arduino with FTDI chip works very well. It always is able to respond to the commands from HMI.

In order to increase accuracy and precision, we need feedback from end effector of the manipulator. This can be achieved by adding position sensors to the manipulator. These sensors will be added in the future project.

The pattern drawings shown in Fig. 10 are redrawn using mathematica plot command. As seen from figure, these plots are perfect drawings which are depicted in Fig. 11. Our final target is to get these perfect drawings by using our low-cost manipulator.
